Week 13

Chi-Square Test

# Learning Objectives

**In this chapter, you learn:**

- How and when to use the chi-square test for contingency tables

# $\chi^2$ TEST FOR THE DIFFERENCE BETWEEN TWO PROPORTIONS

# Contingency Tables

## Contingency Tables

- Useful in situations comparing multiple population proportions
- Used to classify sample observations according to two or more characteristics
- Also called a cross-classification table.

# Contingency Table Example

Left-Handed vs. Gender

Dominant Hand: Left vs. Right

Gender: Male vs. Female

- 2 categories for each variable, so this is called a **2 x 2 table**
- Suppose we examine a sample of 300 children

# Contingency Table Example

Sample results organized in a contingency table:

sample size =  $n = 300$ :

120 Females, 12 were  
left handed

180 Males, 24 were  
left handed

Gender	Hand Preference		
	Left	Right	
Female	12	108	120
Male	24	156	180
	36	264	300

# $\chi^2$ Test for the Difference Between Two Proportions

$H_0: \pi_1 = \pi_2$  (Proportion of females who are left handed is equal to the proportion of males who are left handed)

$H_1: \pi_1 \neq \pi_2$  (The two proportions are not the same – hand preference is **not** independent of gender)

- If  $H_0$  is true, then the proportion of left-handed females should be the same as the proportion of left-handed males
- The two proportions above should be the same as the proportion of left-handed people overall

# The Chi-Square Test Statistic

The Chi-square test statistic is:

$$\chi_{STAT}^2 = \sum_{\text{all cells}} \frac{(f_o - f_e)^2}{f_e}$$

- where:

$f_o$  = observed frequency in a particular cell

$f_e$  = expected frequency in a particular cell if  $H_0$  is true

**$\chi_{STAT}^2$  for the 2 x 2 case has 1 degree of freedom**

(Assumed: each cell in the contingency table has expected frequency of at least 5)

# Decision Rule

The  $\chi^2_{STAT}$  test statistic approximately follows a chi-squared distribution with one degree of freedom

## Decision Rule:

If  $\chi^2_{STAT} > \chi^2_{\alpha}$ , reject  $H_0$ , otherwise, do not reject  $H_0$

# Computing the Average Proportion

The average proportion is:

$$\bar{p} = \frac{X_1 + X_2}{n_1 + n_2} = \frac{X}{n}$$

120 Females, 12 were left handed

180 Males, 24 were left handed

Here:

$$\bar{p} = \frac{12 + 24}{120 + 180} = \frac{36}{300} = 0.12$$

i.e., based on all 300 children the proportion of left handers is 0.12, that is, 12%

# Finding Expected Frequencies

- To obtain the expected frequency for left handed females, multiply the average proportion left handed ( $p$ ) by the total number of females
- To obtain the expected frequency for left handed males, multiply the average proportion left handed ( $p$ ) by the total number of males

---

**If the two proportions are equal, then**

$$P(\text{Left Handed} \mid \text{Female}) = P(\text{Left Handed} \mid \text{Male}) = .12$$

**i.e., we would expect**       **$(.12)(120) = 14.4$  females to be left handed**  
 **$(.12)(180) = 21.6$  males to be left handed**

# Observed vs. Expected Frequencies

Gender	Hand Preference		
	Left	Right	
Female	Observed = 12 Expected = 14.4	Observed = 108 Expected = 105.6	120
Male	Observed = 24 Expected = 21.6	Observed = 156 Expected = 158.4	180
	36	264	300

# The Chi-Square Test Statistic

Gender	Hand Preference		
	Left	Right	
Female	Observed = 12 Expected = 14.4	Observed = 108 Expected = 105.6	120
Male	Observed = 24 Expected = 21.6	Observed = 156 Expected = 158.4	180
	36	264	300

The test statistic is:

$$\chi^2_{STAT} = \sum_{\text{all cells}} \frac{(f_o - f_e)^2}{f_e}$$

$$= \frac{(12 - 14.4)^2}{14.4} + \frac{(108 - 105.6)^2}{105.6} + \frac{(24 - 21.6)^2}{21.6} + \frac{(156 - 158.4)^2}{158.4} = 0.7576$$

# Decision Rule

The test statistic is  $\chi^2_{STAT} = 0.7576$ ;  $\chi^2_{0.05}$  with 1 d.f. = 3.841

## Decision Rule:

If  $\chi^2_{STAT} > 3.841$ , reject  $H_0$ ,  
otherwise, do not reject  $H_0$

Here,

$\chi^2_{STAT} = 0.7576 < \chi^2_{0.05} = 3.841$ ,  
so we **do not reject  $H_0$**  and  
conclude that there is not sufficient  
evidence that the two proportions  
are different at  $\alpha = 0.05$

# $\chi^2$ TEST FOR DIFFERENCES AMONG MORE THAN TWO PROPORTIONS

# $\chi^2$ Test for Differences Among More Than Two Proportions

Extend the  $\chi^2$  test to the case with more than two independent populations:

$$H_0: \pi_1 = \pi_2 = \dots = \pi_c$$

$H_1$ : Not all of the  $\pi_j$  are equal ( $j = 1, 2, \dots, c$ )

# The Chi-Square Test Statistic

The Chi-square test statistic is:

$$\chi^2_{STAT} = \sum_{\text{all cells}} \frac{(f_o - f_e)^2}{f_e}$$

- Where:

$f_o$  = observed frequency in a particular cell of the 2 x c table

$f_e$  = expected frequency in a particular cell if  $H_0$  is true

**$\chi^2_{STAT}$  for the 2 x c case has  $(2 - 1)(c - 1) = c - 1$  degrees of freedom**

(Assumed: each cell in the contingency table has expected frequency of at least 1)

# Computing the Overall Proportion

The overall proportion is:

$$\bar{p} = \frac{X_1 + X_2 + \Lambda + X_c}{n_1 + n_2 + \Lambda + n_c} = \frac{X}{n}$$

- Expected cell frequencies for the  $c$  categories are calculated as in the  $2 \times 2$  case, and the decision rule is the same:

**Decision Rule:**

If  $\chi_{STAT}^2 > \chi_{\alpha}^2$  reject  $H_0$ ,  
otherwise, do not reject  $H_0$

Where  $\chi_{\alpha}^2$  is from the chi-squared distribution with  $c - 1$  degrees of freedom

## Example of $\chi^2$ Test for Differences Among More Than Two Proportions

A University is thinking of switching to a trimester academic calendar. A random sample of 100 administrators, 50 students, and 50 faculty members were surveyed

Opinion	Administrators	Students	Faculty
Favor	63	20	37
Oppose	37	30	13
Totals	100	50	50

Using a 1% level of significance, which groups have a different attitude?

# Chi-Square Test Results

$$H_0: \pi_1 = \pi_2 = \pi_3$$

$H_1$ : Not all of the  $\pi_j$  are equal ( $j = 1, 2, 3$ )

## Chi-Square Test: Administrators, Students, Faculty

	Admin	Students	Faculty	Total	
<b>Favor</b>	63	20	37	120	← Observed
<b>Oppose</b>	37	30	13	80	
<b>Total</b>	100	50	50	200	

Expected

$$\chi_{STAT}^2 = 12.792 > \chi_{0.01}^2 = 9.2103 \text{ so reject } H_0$$

# The Marascuilo Procedure

- Used when the null hypothesis of equal proportions is rejected
- Enables you to make comparisons between all pairs
- Start with the observed differences,  $p_j - p_{j'}$ , for all pairs (for  $j \neq j'$ ) then compare the absolute difference to a calculated critical range

# The Marascuilo Procedure

- Critical Range for the Marascuilo Procedure:

$$\text{Critical range} = \sqrt{\chi_{\alpha}^2} \sqrt{\frac{p_j(1-p_j)}{n_j} + \frac{p_{j'}(1-p_{j'})}{n_{j'}}$$

- (Note: the critical range is different for each pairwise comparison)

- A particular pair of proportions is significantly different if

$$|p_j - p_{j'}| > \text{critical range for } j \text{ and } j'$$

# Marascuilo Procedure Example

A University is thinking of switching to a trimester academic calendar. A random sample of 100 administrators, 50 students, and 50 faculty members were surveyed

<b>Opinion</b>	<b>Administrators</b>	<b>Students</b>	<b>Faculty</b>
<b>Favor</b>	63	20	37
<b>Oppose</b>	37	30	13
<b>Totals</b>	100	50	50

Using a 1% level of significance, which groups have a different attitude?

# Chi-Square Test Results

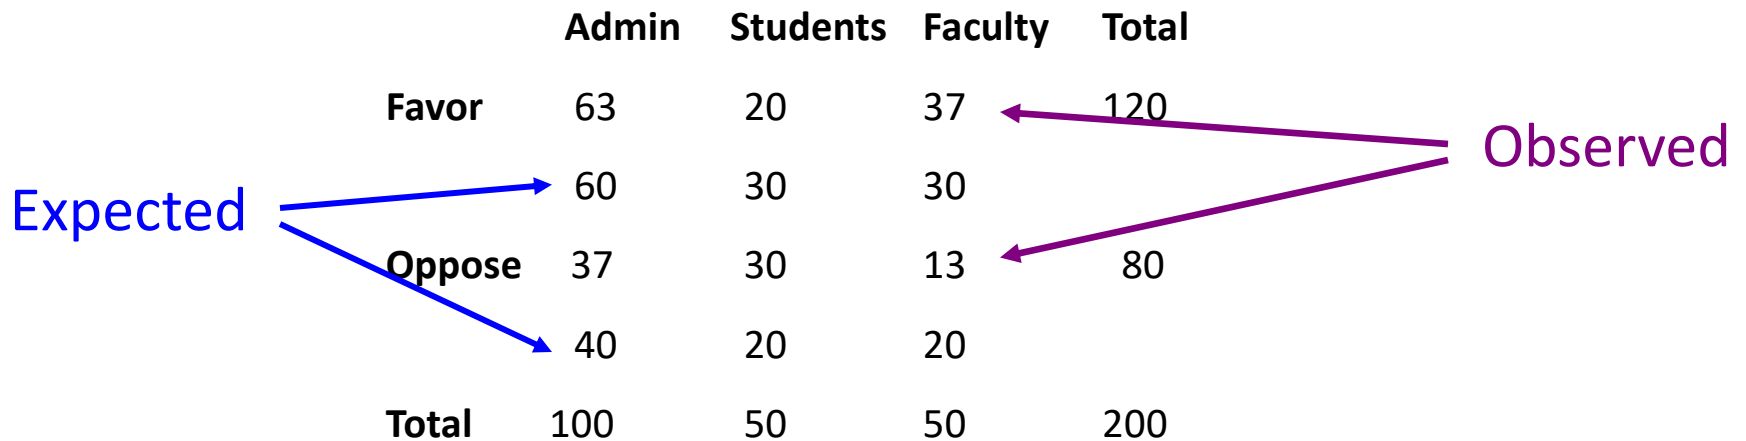

$$H_0: \pi_1 = \pi_2 = \pi_3$$

$H_1$ : Not all of the  $\pi_j$  are equal ( $j = 1, 2, 3$ )

## Chi-Square Test: Administrators, Students, Faculty

	Admin	Students	Faculty	Total	
<b>Favor</b>	63	20	37	120	← Observed
<b>Oppose</b>	37	30	13	80	
<b>Total</b>	100	50	50	200	

Expected

$$\chi_{STAT}^2 = 12.792 > \chi_{0.01}^2 = 9.2103 \text{ so reject } H_0$$

# Marascuilo Procedure: Solution

Calculations In Excel:

Marascuilo Procedure							
Group	Sample Proportion	Sample Size	Comparison	Absolute Difference	Std. Error of Difference	Critical Range	Results
1	0.63	100	1 to 2	0.23	0.084445249	0.2563	Means are not different
2	0.4	50	1 to 3	0.11	0.078606615	0.2386	Means are not different
3	0.74	50	2 to 3	0.34	0.092994624	0.2822	Means are different

compare

At 1% level of significance, there is evidence of a difference in attitude between students and faculty

**Minitab does not do the Marascuilo procedure**

# $\chi^2$ TEST OF INDEPENDENCE

# $\chi^2$ Test of Independence

Similar to the  $\chi^2$  test for equality of more than two proportions, but extends the concept to contingency tables with **r rows** and **c columns**

$H_0$ : The two categorical variables are independent  
(i.e., there is no relationship between them)

$H_1$ : The two categorical variables are dependent  
(i.e., there is a relationship between them)

# $\chi^2$ Test of Independence

The Chi-square test statistic is:

$$\chi^2_{STAT} = \sum_{\text{all cells}} \frac{(f_o - f_e)^2}{f_e}$$

■ where:

$f_o$  = observed frequency in a particular cell of the  $r \times c$  table

$f_e$  = expected frequency in a particular cell if  $H_0$  is true

$\chi^2_{STAT}$  for the  $r \times c$  case has  $(r - 1)(c - 1)$  degrees of freedom

(Assumed: each cell in the contingency table has expected frequency of at least 1)

# Expected Cell Frequencies

- Expected cell frequencies:

$$f_e = \frac{\text{row total} \times \text{column total}}{n}$$

Where:

row total = sum of all frequencies in the row

column total = sum of all frequencies in the column

n = overall sample size

# Decision Rule

- The decision rule is

If  $\chi_{STAT}^2 > \chi_{\alpha}^2$ , reject  $H_0$ ,

otherwise, do not reject  $H_0$

Where  $\chi_{\alpha}^2$  is from the chi-squared distribution with  $(r - 1)(c - 1)$  degrees of freedom

# Example

- The meal plan selected by 200 students is shown below:

Class Standing	Number of meals per week			Total
	20/week	10/week	none	
Fresh.	24	32	14	70
Soph.	22	26	12	60
Junior	10	14	6	30
Senior	14	16	10	40
Total	70	88	42	200

# Example

- The hypothesis to be tested is:

$H_0$ : Meal plan and class standing are independent  
(i.e., there is no relationship between them)

$H_1$ : Meal plan and class standing are dependent  
(i.e., there is a relationship between them)

# Example: Expected Cell Frequencies

Observed:

Class Standing	Number of meals per week			Total
	20/wk	10/wk	none	
Fresh.	24	32	14	70
Soph.	22	26	12	60
Junior	10	14	6	30
Senior	14	16	10	40
Total	70	88	42	200

Expected cell frequencies if  $H_0$  is true:

Class Standing	Number of meals per week			Total
	20/wk	10/wk	none	
Fresh.	24.5	30.8	14.7	70
Soph.	21.0	26.4	12.6	60
Junior	10.5	13.2	6.3	30
Senior	14.0	17.6	8.4	40
Total	70	88	42	200

Example for one cell:

$$f_e = \frac{\text{row total} \times \text{column total}}{n}$$

$$= \frac{30 \times 70}{200} = 10.5$$

# Example: The Test Statistic

- The test statistic value is:

$$\begin{aligned}\chi_{STAT}^2 &= \sum_{\text{all cells}} \frac{(f_o - f_e)^2}{f_e} \\ &= \frac{(24 - 24.5)^2}{24.5} + \frac{(32 - 30.8)^2}{30.8} + \Lambda + \frac{(10 - 8.4)^2}{8.4} = 0.709\end{aligned}$$

$\chi_{0.05}^2 = 12.592$  from the chi-squared distribution  
with  $(4 - 1)(3 - 1) = 6$  degrees of freedom

# Example: Decision and Interpretation

The test statistic is  $\chi^2_{STAT} = 0.709$ ;  $\chi^2_{0.05}$  with 6 d.f. = 12.592

**Decision Rule:**

If  $\chi^2_{STAT} > 12.592$ , reject  $H_0$ ,  
otherwise, do not reject  $H_0$

Here,  
 $\chi^2_{STAT} = 0.709 < \chi^2_{0.05} = 12.592$ ,  
so **do not reject  $H_0$**

**Conclusion:** there is not sufficient  
evidence that meal plan and class  
standing are related at  $\alpha = 0.05$

**EXERCISE**

## 12.14

Apa pendapat warga Amerika mengenai iklan online yang disesuaikan dengan ketertarikan individu? Sebuah survei pada 1.000 orang pengguna internet menyatakan bahwa 55% dari pengguna berusia 18-24 tahun, 59% dari pengguna berusia 25-34 tahun, 66% dari pengguna berusia 35-49 tahun, 77% dari pengguna berusia 50-64 tahun, dan 82% dari pengguna berusia 65-89 tahun menentang penggunaan iklan tersebut. Misalkan survei tersebut dilakukan pada 200 orang responden untuk masing masing kelompok usia. Pada tingkat signifikansi 0,05, apakah terdapat bukti bahwa terdapat perbedaan antara kelompok usia yang menolak penggunaan iklan tersebut?

## 12.16 (Cont'd)

Lebih banyak orang melakukan belanja kebutuhan rumah tangga (*grocery shopping*) pada hari Sabtu jika dibandingkan dengan hari lain dalam seminggu. Namun demikian, apakah terdapat perbedaan proporsi dari mereka yang melakukan *grocery shopping* pada hari Sabtu diantara rentang usia yang berbeda? Sebuah penelitian menunjukkan hasil dari rentang usia yang berbeda, sebagai berikut:

# 12.16

	USIA		
HARI BELANJA UTAMA	Dibawah 35	35–54	Diatas 54
Sabtu	24%	28%	12%
Selain hari Sabtu	76%	72%	88%

Misalkan terdapat 200 orang pada tiap rentang usia yang disurvei. Apakah terdapat bukti perbedaan yang signifikan antara rentang usia tersebut berkaitan dengan hari belanja utama mereka? (Gunakan  $\alpha=0,05$ )

# 12.18

Apakah terdapat kesenjangan generasi dalam musik? Sebuah penelitian melaporkan bahwa 45% dari mereka yang berusia 16 hingga 29 tahun, 42% dari mereka yang berusia 30 hingga 49 tahun, dan 33% dari mereka yang berusia 50 hingga 64 tahun sering mendengar musik rock. Misalkan penelitian tersebut dilakukan pada 200 orang responden untuk masing-masing grup. Apakah terdapat bukti yang menunjukkan perbedaan yang signifikan antar kelompok usia sehubungan dengan proporsi mereka yang sering mendengar musik rock? (Gunakan  $\alpha = 0.05$ )

## 12.24 (cont'd)

Sebuah perusahaan besar ingin mengetahui apakah ada hubungan antara waktu yang dibutuhkan pegawainya untuk melakukan perjalanan rumah-kantor dengan tingkat stres di tempat kerja. Sebuah penelitian pada 166 pekerja memberikan hasil sebagai berikut:

## 12.24 (cont'd)

Waktu Tempuh	Tingkat Stres			
	Tinggi	Sedang	Rendah	Total
Kurang dari 15 Menit	9	5	18	32
14-45 Menit	17	8	28	53
Lebih dari 45 Menit	18	6	7	31
Total	44	19	53	116

## 12.24

Pada tingkat signifikansi 0,01, apakah terdapat bukti hubungan yang signifikan antara waktu tempuh dengan tingkat stres?

**THANK YOU**
